Temperature oxygen squeeze

Conceptual diagram illustrating how change in a water source's oxygen and temperature can restrict the habitat of species.

A small slice of the alcove offers intermediate T-DO conditions that fish select

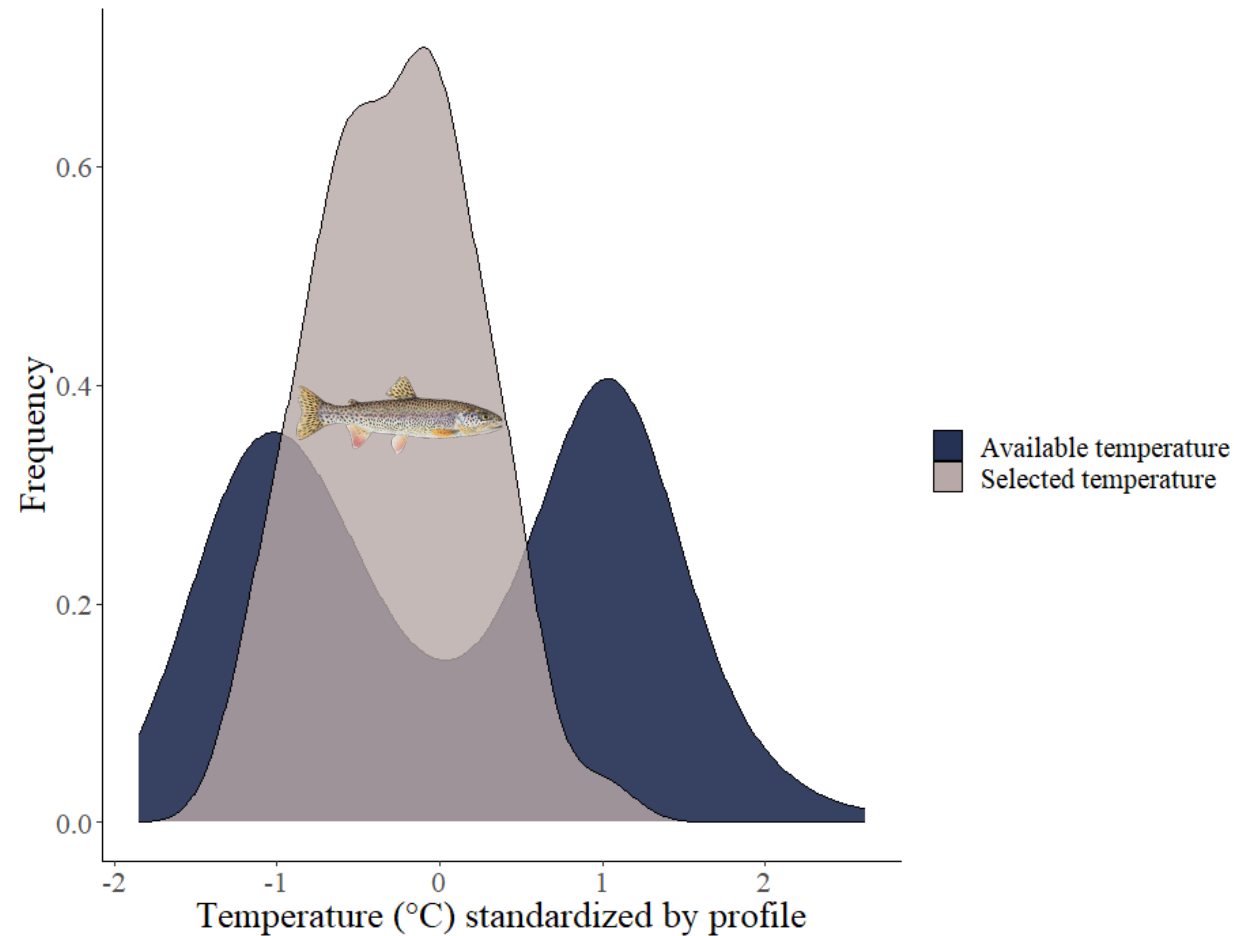

Photo by Jonny Armstrong

Studying fish behavior provides inference on the useable size of these alcoves.

Total alcove - large

Portion with cool water - small

Portion with cool water and high DO - very small

There is a shortcoming of our work so far – we've only sampled during the day...

Diel variation: stressors occur asynchronously

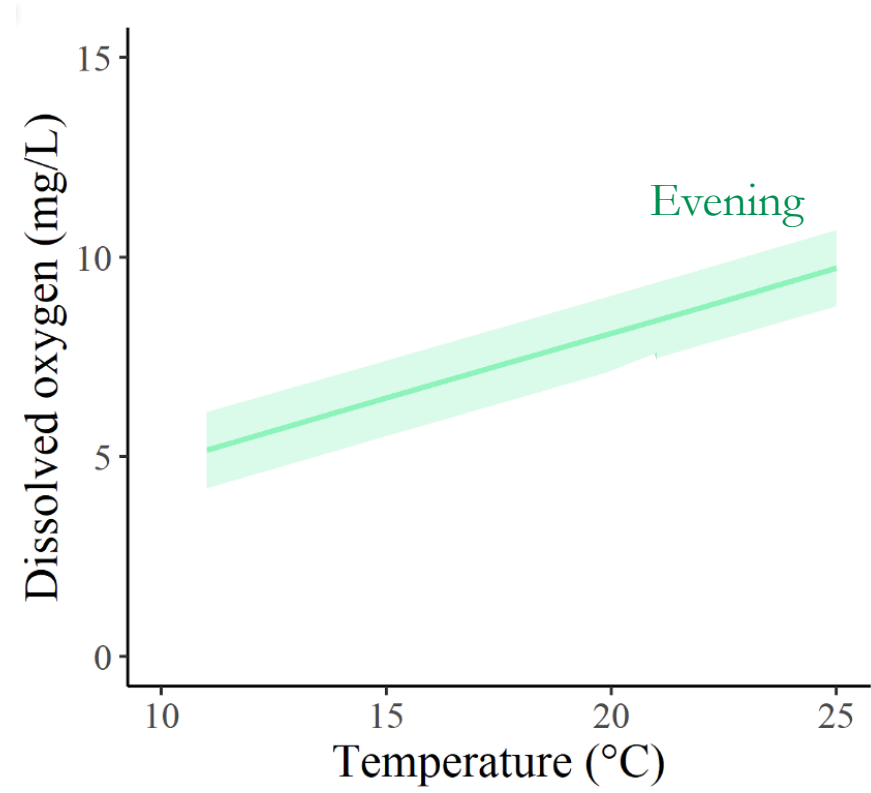

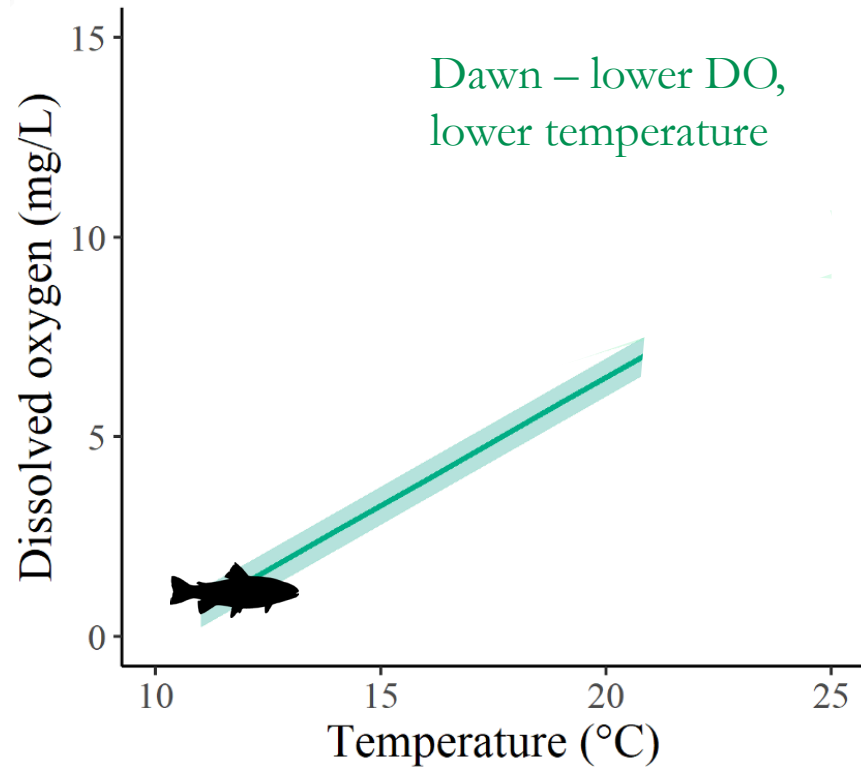

Photo by Lisa Hildebrand

Stressors are asynchronous for fish

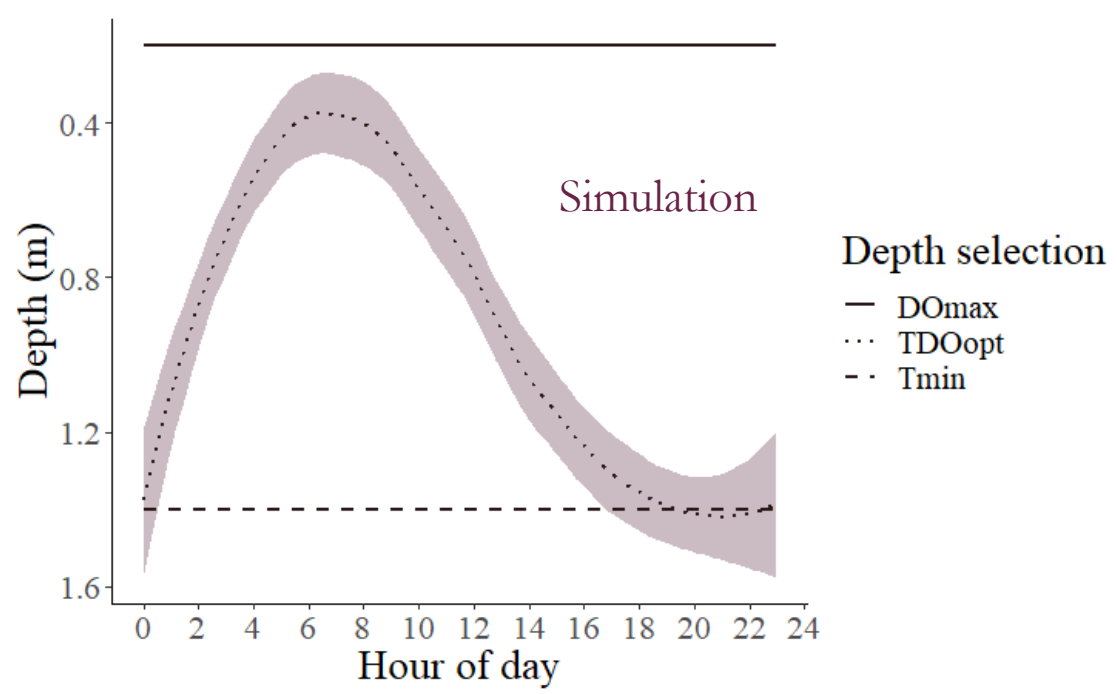

- Night
 - (+) lower temperature
 - (-) lower DO
- Day
 - (-) higher temperature
 - (+) higher DO
- Constraints are toggling – asynchrony softens trade off
- Fish can navigate these trade offs by moving
 - Fine scale diel vertical movement (DVM)

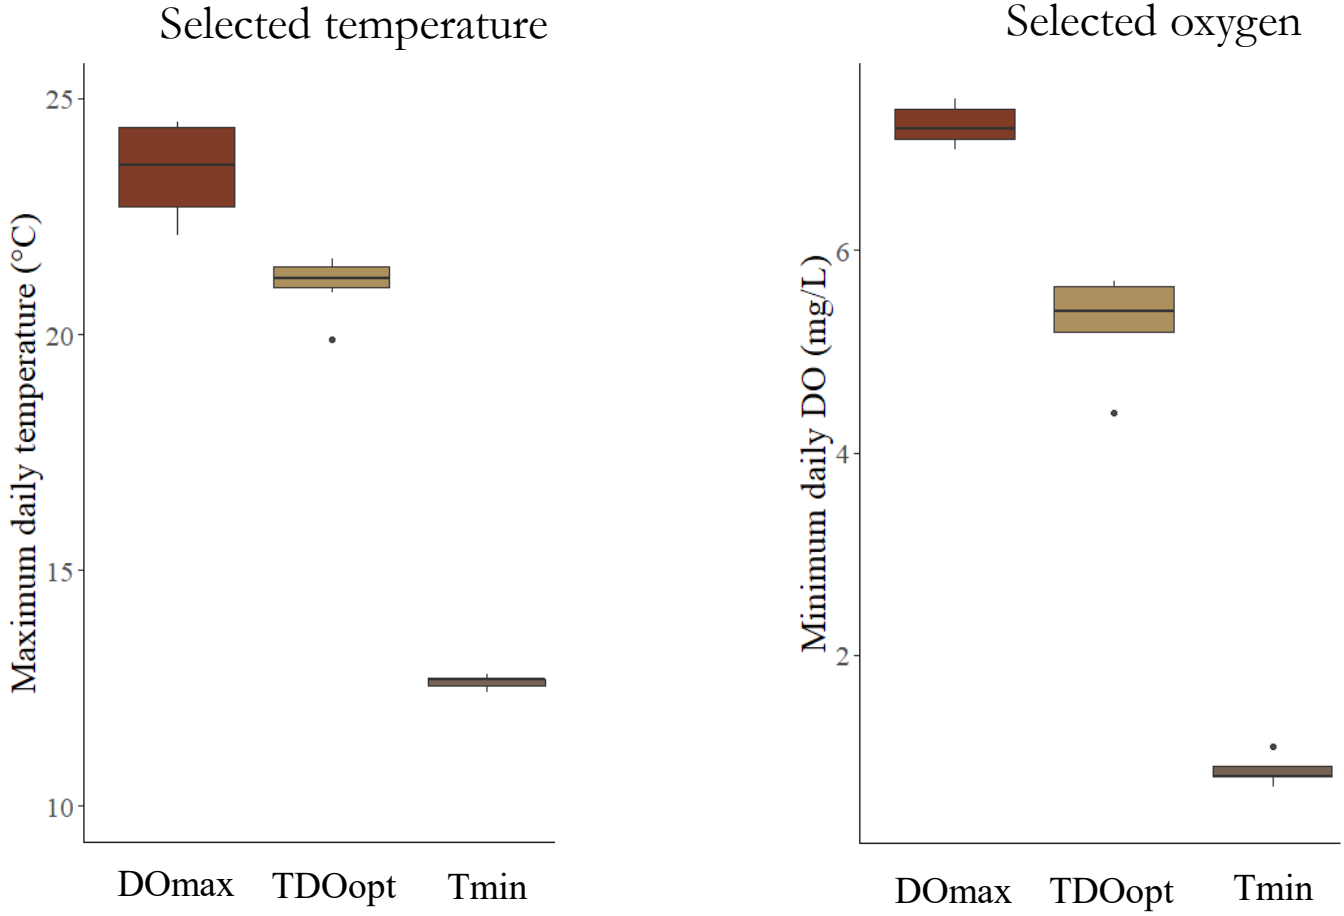

Tagged fish incur low DO in exchange for cold temperatures

Refuges formed by hyporheic upwelling can generate a temperature-oxygen squeeze

In stratified alcoves, intermediate conditions in temperature and oxygen existed in a relatively small boundary layer spanning as little as ~30cm of the water column.

Fish body temperatures indicate limited vertical use of habitat

Oxygen constraints on thermal refuge use may be a blind spot for climate adaptation planning of cold-water fishes – oxygen data is limited compared to temperature data.

Temperature and dissolved oxygen are critical to cold-adapted fishes, and these conditions can vary both spatially and through a 24-hour timeframe

Asynchronous threats of hypoxia and heat stress create a pronounced trade-off for fish, which became more severe at night during the oxygen minimum

Diel vertical migration is an emergent property for fish balancing these dynamic trade-offs
